### 11.1 Simplex Algorithm (Continued)

### 11.1.1 Assumptions

So far we have made the following assumptions:

1. The LP is in the standard form i.e.

$$
\begin{array}{r}
\min c^{T} x \\
\text { s.t } A x=b, \\
x \geq 0
\end{array}
$$

where $C, x \in \mathbb{R}^{n}, A \in \mathbb{R}^{m \times n}, b \in \mathbb{R}^{m}$ and $\operatorname{rank}(A)=m$
2. Every Basic Feasible Solution i.e. BFS is non-degenerate
3. BFS is in the form

$$
\begin{equation*}
[I \mid Y][x]=y_{0} \tag{11.1}
\end{equation*}
$$

where I is $m \times m$ Identity Matrix, $x=\left[\begin{array}{c}x_{B} \\ x_{N B}\end{array}\right], x_{B} \in R^{n}$ and $x_{N B} \in R^{n-m}$

### 11.2 Basic Steps of Algorithm

- Generic step of the algorithm is to swap a basic variable with a non basic variable. For now assume that we have selected basic variable $x_{p}$ and non-basic variable $x_{q}$ to swap
- $x_{p}$ can be swapped with $x_{q}$ if and only if $Y_{p q} \neq 0$ because if $Y_{p q}$ is equal to 0 then column vector $Y_{q}$ can be represented as linear combination of $m 1$ basis vectors i.e.

$$
Y_{q}=\sum_{i=1}^{m} y_{i \neq p} * I_{i}
$$

and hence $Y_{q}$ cannot be included in basic solution

- Now make $q^{\text {th }}$ column as $\left[\begin{array}{lllllll}0 & \ldots & 0 & 1_{p} & 0 & \ldots & 0\end{array}\right]$ where $1_{p}$ signifies 1 at $p^{\text {th }}$ position. For that divide $p_{t h}$ row of matrix $\left[\begin{array}{ll}I & Y\end{array}\right]$ and matrix $[Y(0)]$ by $Y_{p q}$ and apply the row operation $R_{i} \Rightarrow$ $R_{i}-Y_{i q} * R_{p}$

### 11.3 Determining the Leaving Variable p

- While applying row transformation of $\left[\begin{array}{ll}I & Y\end{array}\right]$ rows of $[I]$ also changes and are given by

$$
Y_{i 0}^{\prime}=Y_{i 0}-Y_{i q} * Y_{p 0} / Y_{i 0}
$$

Condition $Y_{i 0}{ }^{\prime} \geq 0$ must satisfy otherwise $x_{q}$ would not be a BFS.

- So choose p such that

$$
p \in S=\underset{i}{\operatorname{argmin}}\left\{Y_{i 0} / Y_{i q} \mid Y_{i q} \geq 0\right\}
$$

- If number of elements in $S$ is $>1$ then the would become degenerate. Since non-degeneracy is assumed

$$
p=\underset{i}{\operatorname{argmin}}\left\{Y_{i 0} / Y_{i q} \mid Y_{i q} \geq 0\right\}
$$

### 11.4 Determining the Entering Variable q

- We Know that

$$
\begin{gathered}
{\left[\begin{array}{ll}
I & Y
\end{array}\right]\left[\begin{array}{c}
x_{B} \\
x_{N B}
\end{array}\right]=[Y(0)]} \\
x_{B}=Y_{0}-Y x_{N B} \\
\text { Where }\left[\begin{array}{c}
x_{B} \\
x_{N B}
\end{array}\right] \geq 0
\end{gathered}
$$

- Initial Cost:

$$
\begin{aligned}
& c^{T}\left[\begin{array}{c}
x_{B} \\
x_{N B}
\end{array}\right] \\
& =c_{B}^{T} x_{B}+c_{N B}^{T} x_{N B} \\
& \\
& =c_{B}^{T} x_{B} \\
& \\
& =c_{B}^{T} Y_{0}
\end{aligned} \text { since } x_{N B}=0 \text { and } I * x_{B}+Y * x_{N B}=Y_{0} \quad l
$$

- Now cost is

$$
\begin{aligned}
& c^{T}\left[\begin{array}{c}
x_{B} \\
x_{N B}
\end{array}\right]=c_{B}^{T} x_{B}+c_{N B}^{T} x_{N B} \\
& =c_{B}^{T}\left(Y_{0}-Y x_{N B}\right)+c_{N B}^{T} x_{N B} \\
& \quad=c_{B}^{T} Y_{0}+\left(c_{N B-Y^{T} c_{B}}\right)^{T} x_{N B}
\end{aligned}
$$

- Now we can choose q such for which $\left(c_{N B}-Y^{T} c_{B}\right)_{q}<0$
- Formalizing the above concept

$$
\left[\begin{array}{cccccccc}
1 & 0 & \ldots & 0 & Y_{1, m+1} & Y_{1, m+2} & \ldots & Y_{1, n} \\
0 & 1 & \ldots & 0 & Y_{2, m+1} & Y_{2, m+2} & \ldots & Y_{2, n} \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \ldots & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \ldots & \cdot \\
\cdot & \cdot & \cdot & \cdot & \cdot & \cdot & \ldots & . \\
0 & 0 & \ldots & 1 & Y_{m, m+1} & Y_{m, m+2} & \ldots & Y_{m, n}
\end{array}\right]\left[\begin{array}{c}
x_{1} \\
\cdot \\
\cdot \\
\cdot \\
x_{m} \\
\cdot \\
\cdot \\
\cdot \\
x_{n}
\end{array}\right]=\left[\begin{array}{c}
y_{10} \\
\cdot \\
\cdot \\
\cdot \\
y_{m 0} \\
\cdot \\
\cdot \\
\cdot \\
y_{n 0}
\end{array}\right]
$$

and

$$
\begin{aligned}
\left(c_{N B}-Y^{T} c_{B}\right)^{T} x_{N B} & =\sum_{j=m+1}^{n}\left(c_{j}-Z_{j}\right) * x_{j} \\
\text { Where } Z_{j} & =\sum_{i=1}^{m}\left(Y_{i, j} * c_{i}\right)
\end{aligned}
$$

- To determine the entering variable choose j such that $\left(c_{j}-Z_{j}\right)<0$

### 11.4.1 Theorem 8.1.

Given a non-degenerate Basic Feasible Solution with objective value $Z^{\prime}$. Suppose $c_{j}-Z_{j}{ }^{\prime}<0$ for some j there is a feasible solution with objective value $<Z^{\prime}$. Also if variable $x_{j}$ can be substituted for a variable in the basis for a new BFS, we get new BFS with value $Z_{0}<0$. If this cannot be done then the solution is unbounded.

### 11.5 Optimality condition

The Basic Feasible Solution is optimal if

$$
\forall, \quad c_{j}-Z_{j} \geq 0
$$

### 11.6 Some Points to Ponder

- f there does not exist $p$ to replace then we have founded the recession direction and the cost can be reduced to $-\infty$
- In the worst case the Simplex Algorithm might visit all the extreme points. Example - Klee Minty cube

### 11.7 Duality

Every linear programming problem, referred to as a primal problem, can be converted into a dual problem, which provides an upper bound to the optimal value of the primal problem. The primal problem is:

$$
\begin{gathered}
\min _{x} c^{T} x \\
A x=b \\
x \geq 0 \\
\text { Where } A \in R^{m \times n}, \operatorname{Rank}(A)=m
\end{gathered}
$$

with the corresponding symmetric dual problem,

$$
\begin{gathered}
\max _{y} b^{T} y \\
A^{T} y \leq c \\
\text { Where } A \in R^{m \times n}, \operatorname{Rank}(A)=m
\end{gathered}
$$
